Title	Particulate matter air pollution components and incidence of cancers of the stomach and the upper aerodigestive tract in the European Study of Cohorts of Air Pollution Effects (ESCAPE)
Article type	Research Paper

Abstract

Introduction: Previous analysis from the large European multicentre ESCAPE study showed an association of ambient particulate matter <math><2.5\mu\text{m}</math> (PM2.5) air pollution exposure at residence with the incidence of gastric cancer. It is unclear which components of PM are most relevant for gastric and also upper aerodigestive tract (UADT) cancer and some of them may not be strongly correlated with PM mass. We evaluated the association between long-term exposure to elemental components of PM2.5 and PM10 and gastric and UADT cancer incidence in European adults. Methods: Baseline addresses of individuals were geocoded and exposure was assessed by land-use regression models for copper (Cu), iron (Fe) and zinc (Zn) representing non-tailpipe traffic emissions; sulphur (S) indicating long-range transport; nickel (Ni) and vanadium (V) for mixed oil-burning and industry; silicon (Si) for crustal material and potassium (K) for biomass burning. Cox regression models with adjustment for potential confounders were used for cohort-specific analyses. Combined estimates were determined with random effects meta-analyses. Results: Ten cohorts in six countries contributed data on 227,044 individuals with an average follow-up of 14.9 years with 633 incident cases of gastric cancer and 763 of UADT cancer. The combined hazard ratio (HR) for an increase of 200 ng/m³ of PM2.5_S was 1.92 (95%-confidence interval (95%-CI) 1.13;3.27) for gastric cancer, with no indication of heterogeneity between cohorts (I²=0%), and 1.63 (95%-CI 0.88;3.01) for PM2.5_Zn (I²=70%). For the other elements in PM2.5 and all elements in PM10 including PM10_S, non-significant HRs between 0.78 and 1.21 with mostly wide CIs were seen. No association was found between any of the elements and UADT cancer. The HR for PM2.5_S and gastric cancer was robust to adjustment for additional factors, including diet, and restriction to study participants with stable addresses over follow-up resulted in slightly higher effect estimates with a decrease in precision. In a two-pollutant model, the effect estimate for total PM2.5 decreased whereas that for PM2.5_S was robust. Conclusion: This large multicentre cohort study shows a robust association between gastric cancer and long-term exposure to PM2.5_S but not PM10_S, suggesting that S in PM2.5 or correlated air pollutants may contribute to the risk of gastric cancer.

Abstract:

Introduction: Previous analysis from the large European multicentre ESCAPE study showed an association of ambient particulate matter $<2.5\mu\text{m}$ ($\text{PM}_{2.5}$) air pollution exposure at residence with the incidence of gastric cancer. It is unclear which components of PM are most relevant for gastric and also upper aerodigestive tract (UADT) cancer and some of them may not be strongly correlated with PM mass. We evaluated the association between long-term exposure to elemental components of $\text{PM}_{2.5}$ and PM_{10} and gastric and UADT cancer incidence in European adults.

Methods: Baseline addresses of individuals were geocoded and exposure was assessed by land-use regression models for copper (Cu), iron (Fe) and zinc (Zn) representing non-tailpipe traffic emissions; sulphur (S) indicating long-range transport; nickel (Ni) and vanadium (V) for mixed oil-burning and industry; silicon (Si) for crustal material and potassium (K) for biomass burning. Cox regression models with adjustment for potential confounders were used for cohort-specific analyses. Combined estimates were determined with random effects meta-analyses.

Results: Ten cohorts in six countries contributed data on 227,044 individuals with an average follow-up of 14.9 years with 633 incident cases of gastric cancer and 763 of UADT cancer.

The combined hazard ratio (HR) for an increase of 200 ng/m³ of $\text{PM}_{2.5_S}$ was 1.92 (95%-confidence interval (95%-CI) 1.13;3.27) for gastric cancer, with no indication of heterogeneity between cohorts ($I^2=0\%$), and 1.63 (95%-CI 0.88;3.01) for $\text{PM}_{2.5_Zn}$ ($I^2=70\%$). For the other elements in $\text{PM}_{2.5}$ and all elements in PM_{10} including PM_{10_S} , non-significant HRs between 0.78 and 1.21 with mostly wide CIs were seen. No association was found between any of the elements and UADT cancer. The HR for $\text{PM}_{2.5_S}$ and gastric cancer was robust to adjustment for additional factors, including diet, and restriction to study participants with stable addresses over follow-up resulted in slightly higher effect estimates with a decrease in precision. In a two-pollutant model, the effect estimate for total $\text{PM}_{2.5}$ decreased whereas that for $\text{PM}_{2.5_S}$ was robust.

Conclusion: This large multicentre cohort study shows a robust association between gastric cancer and long-term exposure to $\text{PM}_{2.5_S}$ but not PM_{10_S} , suggesting that S in $\text{PM}_{2.5}$ or correlated air pollutants may contribute to the risk of gastric cancer.

65
66 **(Running title:** particulate matter elemental components and gastric and UADT cancers)
67

68
69 **Highlights:**

- 70 • Population-based cohorts from 6 European countries (227,044 participants)
- 71 • Copper, iron, zinc, sulphur, nickel, vanadium, silicon and potassium in PM_{2.5} and PM₁₀ were
72 studied
- 73 • Statistically significant strong association of gastric cancer with sulphur in PM_{2.5}, but not in
74 PM₁₀
- 75 • No association of gastric cancer with any of the other 7 elements tested
- 76 • No association with upper aerodigestive tract cancer

87 **Abstract:**

88 **Introduction:** Previous analysis from the large European multicentre ESCAPE study showed an
89 association of ambient particulate matter <2.5µm (PM_{2.5}) air pollution exposure at residence with the
90 incidence of gastric cancer. It is unclear which components of PM are most relevant for gastric and
91 also upper aerodigestive tract (UADT) cancer and some of them may not be strongly correlated with
92 PM mass. We evaluated the association between long-term exposure to elemental components of
93 PM_{2.5} and PM₁₀ and gastric and UADT cancer incidence in European adults.

94 **Methods:** Baseline addresses of individuals were geocoded and exposure was assessed by land-use
95 regression models for copper (Cu), iron (Fe) and zinc (Zn) representing non-tailpipe traffic emissions;
96 sulphur (S) indicating long-range transport; nickel (Ni) and vanadium (V) for mixed oil-burning and
97 industry; silicon (Si) for crustal material and potassium (K) for biomass burning. Cox regression
98 models with adjustment for potential confounders were used for cohort-specific analyses. Combined
99 estimates were determined with random effects meta-analyses.

100 **Results:** Ten cohorts in six countries contributed data on 227,044 individuals with an average follow-
101 up of 14.9 years with 633 incident cases of gastric cancer and 763 of UADT cancer.

102 The combined hazard ratio (HR) for an increase of 200 ng/m³ of PM_{2.5}_S was 1.92 (95%-confidence
103 interval (95%-CI) 1.13;3.27) for gastric cancer, with no indication of heterogeneity between cohorts
104 (I²=0%), and 1.63 (95%-CI 0.88;3.01) for PM_{2.5}_Zn (I²=70%). For the other elements in PM_{2.5} and all
105 elements in PM₁₀ including PM₁₀_S, non-significant HRs between 0.78 and 1.21 with mostly wide CIs
106 were seen. No association was found between any of the elements and UADT cancer. The HR for
107 PM_{2.5}_S and gastric cancer was robust to adjustment for additional factors, including diet, and
108 restriction to study participants with stable addresses over follow-up resulted in slightly higher effect
109 estimates with a decrease in precision. In a two-pollutant model, the effect estimate for total PM_{2.5}
110 decreased whereas that for PM_{2.5}_S was robust.

111 **Conclusion:** This large multicentre cohort study shows a robust association between gastric cancer
112 and long-term exposure to PM_{2.5}_S but not PM₁₀_S, suggesting that S in PM_{2.5} or correlated air
113 pollutants may contribute to the risk of gastric cancer.

116

117

118 **Introduction**

119 Long-term exposure to ambient air pollution with particles contributes to increased cancer risk
120 (International Agency for Research on Cancer Monograph Working Group, 2015), with most evidence
121 for lung cancer (Raaschou-Nielsen et al., 2013).

122 A previous analysis of the large European multicentre ESCAPE study showed an association of
123 particulate matter <2.5µm (PM_{2.5}) exposure at residence with the incidence of gastric cancer (Nagel et
124 al, 2018). For the incidence of upper aerodigestive tract (UADT) cancer, which summarises
125 anatomically closely related sites, no association with PM_{2.5} or PM₁₀ was found (Nagel et al, 2018).

126 PM constitutes a complex mixture depending on contributing sources and atmospheric processes, and
127 it is still not clear which PM components are the most relevant for health, which may vary by
128 endpoints. Although we did not find any association of PM mass with UADT cancer in our earlier
129 work, it cannot be excluded that some components which may not be strongly correlated with PM
130 mass may still have a role in carcinogenesis of UADT cancers.

131 The identification of elemental components of PM air pollution increasing cancer risk may increase
132 our understanding of pathomechanisms and contribute to the identification of specific sources of
133 relevance (Kelly and Fussell, 2012). Components of outdoor air pollutions for which adverse health
134 effects have been reported to include metals, inorganic components, secondary aerosols (sulphate,
135 nitrate) and organic components (de Hoogh et al., 2013). The fact that these components do not occur
136 in isolation, but in a temporally and spatially variable air pollution mix, renders epidemiological
137 studies of individual components complex. While the focus has mostly been on traffic exhaust related
138 components so far, recent reviews have pointed out the possible role of non-exhaust related particle
139 components (Kelly and Fussell, 2015). For example, transition metals such as copper (Cu) and iron
140 (Fe) resulting from brake and tyre wear are likely to promote inflammation and oxidative stress
141 (Hampel et al., 2015). While elements may have health effects per se, some of them also originate

237
238
239 142 predominantly from certain sources (Viana et al., 2008) and may as indicators for the related pollution
240
241 143 mix inform on effective preventions measures. To date, research on the influence of long-term
242
243 144 exposure to different air-borne elements is scarce.
244
245 145 The objective of this study was therefore to investigate the association of chronic exposure to
246
247 146 elemental components of PM air pollution with the incidence of gastric and UADT cancer. The study
248
249 147 was performed in the framework of ESCAPE and the European study of Transport-related Air

354

169 Therefore, 7 study estimates contributed to the meta-analysis (Table 1, for cohort-specific details see
170 (Nagel et al, 2018).

171 Recruitment of the cohorts occurred largely in the 1990s. The cohort studies and the use of their data
172 in ESCAPE were approved by the local ethical and data protection authorities.

173
174

176 **Figure 1:** Location of participating cohorts: Oslo: HUBRO; Stockholm: CEANS (comprising SNAC-
177 K, SALT, Sixty and SDPP); Copenhagen: DCH; Netherlands: EPIC Netherlands; Vorarlberg:
178 VHM&PP; Turin: EPIC Turin; Rome: SIDRIA; For acronyms of cohorts see Methods section.

355
356
357 180 *Outcome definition*
358

359 181 Follow-up was based on linkage to national or local cancer registries, with exception of SIDRIA Rome
360
361 182 for which hospital discharge and mortality register data were used. The main outcomes were all
362
363 183 cancers of the stomach and of the UADT, respectively. Secondary analyses addressed cancer of the
364
365 184 cardia, and adenocarcinomas and squamous-cell carcinomas of the UADT. Carcinomas were identified
366
367 185 using the International Statistical Classification of Diseases and Related Health Problems, 9th and 10th
368
369 186 revision [ICD9 and ICD10]: for gastric cancer C16 [ICD10] and 151 [ICD9], and for UADT cancers:
370
371 187 C01-06 and 141-145 (oral cavity), C09, C10 (oropharynx), C12, C13 (hypo-pharynx) and 146
372
373 188 (pharynx), C14, C32 and 161 (larynx), C15 and 150 (esophagus). Lymphomas/myelomas/leukemias
374
375 189 were excluded according to the International Classification of Diseases for Oncology (ICDO-3)
376
377 190 morphology codes: 9590-9989. We only included primary cancers and only malignant tumors with the
378
379 191 fifth digit of the ICDO morphology code being “3”.

380
381 192
382 193 *Exposure assessment*
383

384 194 Exposures at the residential baseline address of the participants were determined according to a
385
386 195 standardized procedure by assigning air pollution exposure estimates derived from land use regression
387
388 196 (LUR) models specifically developed for the respective areas (de Hoogh, 2013). If a subject moved the
389
390 197 new address was not taken into account except for exclusion of these subjects in a sensitivity analyses
391
392 198 (see below). A detailed description of the 3-step procedure is found elsewhere. First, dedicated
393
394 199 measurement campaigns (three two-week periods over one year) were carried out at 20 locations in
395
396 200 each study area for a one-year period between October 2008 and May 2011. Results from the three
397
398 201 measurements per site were averaged to a mean annual concentration, adjusting for temporal trends
399
400 202 using data from a background monitoring site with continuous data
401
402 203 Second, we collected information about potential predictor variables relating to nearby traffic
403
404 204 intensity, population/household density and land use from Geographic Information Systems (GIS), and
405
406 205 evaluated these to explain spatial variation of measured annual average concentrations using
407
408 206 regression modelling (Beelen et al., 2013; Eeftens et al., 2012). These LUR models were used to
409
410 207 estimate the exposure at the baseline address of each cohort member.

414
415
416 208 To determine the chemical elements contained in the respective PM fractions, PM filters were sent to
417
418 209 Cooper Environmental Services (Portland, OR, USA) to analyse elemental composition using X-
419
420 210 Ray Fluorescence (XRF). As indicators mainly of non-tailpipe traffic emissions such as brake and
421
422 211 tyre wear, Cu, Fe and zinc (Zn) were selected; sulphur (S) mainly for long-range transport; nickel
423
424 212 (Ni) and vanadium (V) for mixed oil-burning and industry; silicon (Si) for crustal material and
425
426 213 potassium (K) for biomass burning (de Hoogh et al., 2013; Viana et al., 2008). However, each
427
428 214 element can have multiple sources. The LUR model results for all study areas have been shown
429
430 215 previously (de Hoogh et al., 2013). Land use regression models for Cu, Fe, and Zn in both
431
432 216 fractions (PM_{10} and $PM_{2.5}$) had average cross-validation explained variance (r^2) between 52% and
433
434
435 217 84% with a large variability between areas (Raaschou-Nielsen et al., 2016). Models for the other
436
437 218 elements performed moderately with average cross-validation r^2 generally between ~50% and
438
439 219 ~60%. For $PM_{2.5}$ S the average cross-validation r^2 was 32% with a range from 2 to 67%, consistent
440
441 220 with the relatively low spatial variation of $PM_{2.5}$ concentrations within the cohort areas. LUR-
442
443 221 models could not be developed for K in PM_{10} (HUBRO), Ni in PM_{10} (HUBRO), Ni in $PM_{2.5}$
444
445 222 (CEANS), V in $PM_{2.5}$ (HUBRO, VHM&PP) and Si in $PM_{2.5}$ (HUBRO).
446

447 223

449 224 *Statistical analyses*

451 225 Cohort-specific analyses were carried out using a common protocol and a centrally developed Stata
452
453 226 analysis script (Nagel et al, 2018). In the cases where data of multiple cohorts were pooled (the
454
455 227 Swedish and the Dutch cohorts, respectively) the analyses were performed stratifying the Cox Model
456
457 228 for a cohort indicator variable.

459 229

461 230 Cox proportional hazard-regression with age as the underlying time-axis was carried out. The hazard
462
463 231 ratio was modeled as an exponential function of continuous exposure. Censoring was applied at the
464
465 232 time of death, a diagnosis of any other cancer (except non-melanoma skin cancer) or end of follow-up,
466
467 233 whichever came first. Model checks included a test for deviation from proportional hazard assumption
468
469 234 and testing the linearity assumption in the relation between each exposure and the log hazard of the

473
474
475 235 outcome by replacing the linear term with a natural cubic spline with two inner knots placed at the 33rd
476
477 236 and 66th percentiles. The model fits of the linear and the spline models were compared using a
478
479 237 likelihood-ratio test (Chi-square test with 2df).

480
481 238
482
483 239 Confounder sets were determined *a priori* with increasing levels of adjustment, following the
484
485 240 procedures of previous ESCAPE studies (Nagel et al, 2018). Model 1 was adjusted for age (time
486
487 241 scale), calendar year of enrolment and sex. Model 2 was additionally adjusted for baseline information
488
489 242 on smoking status, smoking intensity, smoking duration, occupational exposure, employment status
490
491 243 and educational level. Model 3 (the main model) was in addition adjusted for area-level (residential
492
493 244 neighbourhood or similar) socio-economic status (SES). The availability of these variables varied
494
495 245 slightly between cohorts (Nagel et al, 2018). Only complete case analyses were performed. In the few
496
497 246 cases where one variable was missing entirely, the cohort was nevertheless analysed using the
498
499 247 available confounders. In sensitivity analyses we included additional potential confounders (alcohol
500
501 248 consumption, environmental tobacco smoke (ETS), intake of fruit, intake of meat and marital status),
502
503 249 restricted the analysis to participants with stable residence during follow-up or for at least 10 years,
504
505 250 and included an indicator for urban/rural environment to the main model.

506 251 All cohort-specific analyses were done in Stata versions 10 to 14 (StataCorp, College Station, TX).

507
508 252
509
510 253 The results obtained from the cohort-specific analyses were combined with random effects meta-
511
512 254 analysis (DerSimonian and Laird, 1986). Heterogeneity between cohorts was tested by the χ^2 test from
513
514 255 Cochran's Q statistic and quantified with the I^2 (Higgins and Thompson, 2002). Stata version 14
515
516 256 (StataCorp) was used for meta-analyses.

517
518 257
519 258 **Results:**
520
521 259 The cohorts contributed together data on 227,044 individuals with an average follow-up time of 14.9
522
523 260 years. 633 incident cases of gastric cancer and 763 of UADT cancer occurred. DCH and VHM&PP
524
525 261 contributed with most of the cases (Table1). Mean age at baseline in the cohorts ranged from 43 years

262 (VHM&PP) to 57 years (DCH). The details of each cohort including participants characteristics and
263 availability of variables have been reported previously (Nagel et al, 2018).
264
265 There was a wide range of annual mean concentrations of PM elements concentrations within and
266 between study cohorts. Generally, the Nordic countries showed the lowest and the Southern countries
267 the highest levels of PM (Table 1) and similarly for most of the elements, less consistent for Ni, V and
268 Zn. Si had relatively high values in Sweden, S in the Netherlands, and Austria showed high levels of K
269 in PM_{2.5} (Fig. 2 and Figure in the online Supplementary Material). For PM_{2.5} differences in individual
270 exposures were highest in SIDRIA (Rome) for Cu, Fe, K, in EPIC Turin and Netherlands for Ni and S,
271 in EPIC-Netherlands for V and Zn and in CEANS (Stockholm) for Si. The pattern for PM₁₀ was very
272 similar. Correlations of PM elements with total PM_{2.5} and PM₁₀ varied between location with median
273 correlation coefficients largely between 0.4 and 0.6 (Raaschou-Nielsen et al., 2016).
274 In the tests of loglinearity of the dose-response, the p-value of only 4 were ≤ 0.05 and only 8 ≤ 0.1 . P-
275 values of less than 0.05 were observed for DCH for PM_{2.5}_S, for EPIC-Turin for PM₁₀_K and for
276 VHM&PP and SIDRIA for PM₁₀_Si Therefore we took over the results for the linear models for all
277 cohorts and pollutants and consider that this is a valid approximation.

278

591
 279 **Table 1:** Participants, gastric and UADT cancer cases and mean PM_{2.5} concentrations in each cohort
 592

					Incident cases		Exposure	Persons with stable residence (at least 10 years at baseline address)	
	Total participants	Baseline period	Mean follow-up time	Age at baseline (years)	Gastric Cancer	UADT cancer	PM _{2.5} (µg/m ³)	Proportion	Proportion among cases

292 The meta-analysis results from the main model for PM_{2.5} components showed effect estimates above
293 and below unity. Only the positive association of PM_{2.5}_S with gastric cancer incidence was
294 statistically significant with a hazard ratio (HR) of 1.93 (95%-confidence interval (95%-CI) 1.13;3.27)
295 for an increase of 200 ng/m³ (Table 2, Figure 3) with no heterogeneity in cohort results.
296

297 **Figure 3:** Risk for gastric cancer associated with PM_{2.5}_S in each cohort study
298 Hazard ratios according to PM_{2.5}_S in each of the cohort studies, based on confounder model 3.
299 Weights are from random effects analysis. Data points show HR; lines show 95% CI, boxes show the
300 weight with which each cohort contributed to the overall HR; vertical bold line shows overall HR.
301 HR=hazard ratio. PM_{2.5}=particulate matter with diameter <2.5µm.
302
303
304

305 The second highest HR was seen for PM_{2.5}_Zn with 1.63 (95%-CI 0.88;3.01) for an increase of
306 10ng/m³ with heterogeneity between cohorts (I²=70%) No clear association was found with UADT
307 cancers for any of the PM_{2.5} elements. Effect estimates from the age-sex adjusted and fully adjusted
308 confounder model did not differ substantially. Also no clear association could be seen between any of
309 the PM₁₀-components and gastric or UADT cancer incidence (Table in the online Supplementary

732
733
734 310 Material). The association for PM_{10_S} with gastric cancer was 0.97 (95%-CI 0.67;1.41) for an increase
735
736 311 of 200ng/m³, also with no heterogeneity between cohorts. Excluding VHM&PP which had a weight of
737
738 312 66% and 71%, in the meta-analysis of PM_{2.5_S} and PM_{10_S}, respectively, yielded a combined HR of
739
740 313 2.75 (95%-CI 1.10;6.86) and 1,43 (95%-CI 0,72;2.85), respectively. Excluding the three cohorts
741
742 314 (HUBRO, CEANS, EPIC-Netherlands) with a leave-one-out cross-validation (LOOCV) R² below 0.3
743
744 315 for the LUR-models yielded a HRR of 1,74 (95%-CI 0,90;3.33).
745
746 316 The results for the association of PM_{2.5_S} with gastric cancer were robust to further adjustment for
747
748 317 dietary variables and ETS showing no change in the HR obtained for the respective cohorts in this
749
750 318 analysis of 1.83 (95%-CI 1.05;3.20), (Figure 4, additional confounder data available for 6 cohorts).
751
752 319 Similarly, adjustment for the rural indicator yielded very similar effect estimates (information
753
754 320 available in 5 cohorts). Restriction to the population with a stable residence, which is less subject to
755
756 321 misclassification of long-term exposure at the residence, resulted in slightly increased effect estimates,
757
758 322 however with wider CIs.
759
760 323 In two-pollutant models, the effect estimated for total PM_{2.5} changed from 1.36 (95%-CI 0.97;1.90) to
761
762 324 1.07 (95%-CI 0.70;1.64) when adjusted for PM_{2.5_S} and to 1.42 (95%-CI 0.68;2.95) when adjusted for
763
764 325 PM_{2.5_Zn}. The effect estimated for PM_{2.5_S} changed from 1.93 (95%-CI 1.13;3.27) to 1.79 (95%-CI
765
766 326 0.96;3.37) when adjusted for total PM_{2.5} and the estimate for PM_{2.5_Zn} was not affected.

Figure 4: Results of sensitivity analyses for the association of gastric cancer with PM_{2.5_S}. Hazard ratios (HR) with 95% confidence intervals are shown. N= number. The additional confounders were alcohol consumption, environmental tobacco smoke (ETS), intake of fruit, intake of meat and marital status where available.

891
892
893 **341 Discussion**
894

895 **342** This study including cohorts from 6 European countries shows a statistically significant robust
896
897 **343** association of PM_{2.5}_S with gastric cancer incidence. The effect estimate for PM_{2.5} decreased
898
899 **344** markedly when adjusted for PM_{2.5}_S whereas the estimate for the latter changed little. No further
900
901 **345** statistically significant association of the elementary compounds with gastric or UADT cancer was
902
903 **346** observed, including PM₁₀_S.
904

905 **347**
906
907 **348** The identification of PM_{2.5}_S as the element most strongly associated with gastric cancer is in
908
909 **349** agreement with previous analyses within the ESCAPE study on all-cause mortality (Beelen et al.,
910
911 **350** 2015) and lung cancer incidence (Raaschou-Nielsen et al., 2016). In our analysis of gastric cancer, the
912
913 **351** HR for PM_{2.5}_S was larger than for all-cause mortality (HR 1.14) and lung cancer (HR 1.34). In
914
915 **352** contrast to lung cancer, our estimate for gastric cancer was robust when additionally adjusted for
916
917 **353** smoking status, smoking intensity, smoking duration, occupational exposure, employment status,
918
919 **354** educational level, and for area-level (residential neighbourhood or similar) socio-economic status (area
920
921 **355** SES). However, it is of concern that there was no corresponding association seen for PM₁₀_S in
922
923 **356** contrast to PM_{2.5}_S. In general, PM_{2.5} component mass makes up large amount of PM₁₀ component
924
925 **357** mass and sulphates are mainly present in the PM_{2.5} fraction (Tsai et al., 2015). Indeed, the actual
926
927 **358** concentrations measured at the monitoring sites used to develop the LUR models were highly
928
929 **359** correlated (median within area $r = 0.8$) (Tsai et al., 2015). At the cohort address, we found a moderate
930
931 **360** correlation (median=0.57) between predicted PM_{2.5}_S and PM₁₀_S exposures from the LUR. In the
932
933 **361** large VHM&PP cohort, the correlation was identical for measured and modelled concentrations. The
934
935 **362** lower correlation is likely due to relatively moderate performance of the LUR models for S (de Hoogh
936
937 **363** et al., 2013) and possibly the overrepresentation of traffic locations at the monitoring sites compared
938
939 **364** to the cohort addresses. Overall, the explained variance of PM₁₀_S models was slightly higher than
940
941 **365** for PM_{2.5}_S LUR models (de Hoogh et al., 2013). The low variability of S within study areas likely
942
943 **366** has contributed to moderate performance (de Hoogh et al., 2013). In both the mortality and lung
944
945 **367** cancer studies (Beelen et al., 2015; Raaschou-Nielsen et al., 2016), HRs for PM₁₀_S, were above
946
947 **368** unity, but smaller and less consistent than for PM_{2.5}_S.
948
949

950
951
952 369 For gastric cancer, the null finding for PM₁₀_S parallels the null-finding for total PM₁₀ that we have
953
954 370 found in our previous ESCAPE analysis (Nagel et al, 2018).
955
956 371
957
958 372 Overall, our results for PM_{2.5}_S were robust as sensitivity analyses did not notably change the effect
959
960 373 estimate. Restricting the analyses to persons who lived at least 10 years at their baseline address
961
962 374 resulted in slightly increased HRs, which would be expected if the association is true and causal
963
964 375 because the degree of non-differential misclassification of exposure is expected to be lower in this sub-
965
966 376 population. Excluding the most influential cohort, VHM&PP with a weight of 66%, increased the HR.
967
968 377 Although two-pollutant models should be interpreted with caution (Mostofsky et al., 2012), our
969
970 378 finding that the HR in association with PM_{2.5}_S is robust when adjusting for PM_{2.5}, which in turn is
971
972 379 reduced to virtually no effect, is strengthening our result. Even more so, because in contrast to earlier
973
974 380 studies where S and PM were strongly correlated, the moderate correlation in our study (mean of 0.55)
975
976 381 allows us to be more confident to disentangle effects.
977
978 382 Nevertheless, PM_{2.5}_S may also be seen as a marker of a certain pollutant mix. Sources of S are coal,
979
980 383 residual oil and motor vehicle fuels. In the NPACT project, the coal combustion source category
981
982 384 showed the strongest associations of all investigated sources with long-term effects (mortality in
983
984 385 humans and aortic plaque progression in mice) (Lippmann et al., 2013).
985
986 386
987 387 Ashely et al. reported a correlation between SO₂ exposure and gastric cancer mortality in the UK
988
989 388 (Ashley, 1969). This study showed that regions with coal and textile industry had higher gastric cancer
990
991 389 mortality. Another study showed that workers exposed to SO₂ in the pulp and paper industry had no
992
993 390 increased risk of gastric cancer, but mortality from gastric cancer showed a positive dose-response
994
995 391 with increasing exposure, however, with very imprecise estimates (Lee et al., 2002).
996
997 392 While an earlier review on toxicological results postulated that there is little evidence that sulphate in
998
999 393 ambient concentration is toxicologically relevant (Schlesinger and Cassee, 2003), recent reviews
1000
1001 394 acknowledge that it is unclear which effects are related to sulphates contained in the PM-mixture: the
1002
1003 395 cationic elements (H⁺, and therefore acidity, and notably (transition) metals) or adsorbed compounds
1004
1005 396 like polyaromatic hydrocarbons (PAH)) may explain the observed epidemiological associations

397 (Cassee et al., 2013; Reiss et al., 2007). A study in Hong Kong (Wong et al., 2012) that investigated
398 the effects of limiting the sulphur content in fuel found that natural mortality was reduced, however
399 the reduction in SO₂ was highly correlated with reductions in V and Ni and was not statistically
400 significant after adjustment. In our study these metals (V and Ni from residual oil combustion e.g.
401 from industry) were not associated with gastric cancer incidence, although one might argue that the
402 corresponding LUR-models suffered from a lack of sufficiently specific predictors (Beelen et al.,
403 2015).

404
405 The possible pathomechanisms of carcinogenicity of sulphate in ambient air for gastric cancer are not
406 clear. Results from experimental research with human bronchial epithelial cells, support the hypothesis
407 that SO₂ derivatives could by activation of pro-oncogenes and the inactivation of tumour suppressor
408 genes play a role in the pathogenesis of cancer (Qin and Meng, 2009). It can also be speculated
409 whether the formation of sulphuric acid, which is formed from oxidation from SO₂, increases the risk
410 of gastric cancer (Bernatsky et al., 2017). As pointed out above, sulphate may indirectly affect health
411 by e.g. co-occurring transition metals. The bioavailability of these metals may increase (Cassee et al.,
412 2013) and they can lead to the formation of reactive oxygen species (ROS) which in turn may result in
413 oxidative DNA-damage (Møller et al., 2008; Risom et al., 2005).

414
415 Strengths and limitations:

416 Our study comprises data from several cohorts from 7 geographical areas, and constitutes the largest
417 data set to date for the analysis of PM-elements in relation to gastric cancer. A strength is the common
418 standardized exposure assessment protocol that estimates local concentrations with a small scale
419 resolution. Our analysis was able to take into account important individual confounders, especially
420 smoking. We could also adjust for nutritional variables in 4 of the 7 study-specific effect estimates, but
421 cannot rule out residual confounding. While we cannot exclude the possibility of some
422 misclassification due to the measurement campaigns taking place after recruitment of cohort
423 participants, we were, however, able to take into account information on residential stability, which
424 would tend to decrease the degree of exposure misclassification.

1068
1069
1070 425 We were not able to take into account the mobility of the individuals, but had to rely on exposure
1071
1072 426 estimates for the residential address at enrolment into the cohorts. Also, the LUR-model approach does
1073
1074 427 involve some degree of misclassification, and especially the performance of the models for PM_{2.5}
1075
1076 428 were among the lowest when evaluated by leave-one-out crossvalidation, presumably because of the
1077
1078 429 small measured within-study area contrasts. The average leave-one-out cross-validation (LOOCV) R²
1079
1080 430 in the present study with data from 7 geographical areas ranged between 7 and 61% for PM_{2.5}_S, with
1081
1082 431 the highest values in DCH (61%) and VHM&PP (53%) and the lowest in HUBRO. The sensitivity
1083
1084 432 analyses excluding studies with a (LOOCV) R² yielded an only mildly attenuated effect estimate with
1085
1086 433 a widened confidence interval, resulting from the exclusion of three of the seven cohorts. . It is not
1087
1088 434 clear whether the mild change is related to the LOOCV or other characteristics of the cohorts. We
1089
1090 435 further note that the I² statistic of the overall analysis is 0%, suggesting that the variability in estimates
1091
1092 436 across cohorts is mostly due to random error.

1093
1094 437 Overall, we would expect the misclassification related to low LOOCV R² to be non-differential and
1095
1096 438 therefore to induce a bias towards the null-effect. Also the relatively poor model fit would not
1097
1098 439 contribute to an erroneously increased effect estimate in the two-pollutant model: indeed, if two
1099
1100 440 pollutants are of similar influence, the pollutant for which the concentrations are more precisely
1101
1102 441 estimated would yield the higher effect estimate. This is unlikely to be the case here, because the
1103
1104 442 model fit for PM_{2.5} mass was better than for PM_{2.5}_S with validation R² ranging from 42% to 78%.
1105
1106 443 In this analysis we tested 32 outcome-exposure combinations, so a chance finding due to multiple
1107
1108 444 testing cannot be fully excluded. Nevertheless, the robustness of the results and the fact that 6 of the 7
1109
1110 445 cohort estimates were greater than one indicates that the result for S in PM_{2.5} is probably not due to
1111
1112 446 chance. However, clearly additional specific studies are needed.

1113 447
1114
1115 448 Taken together, our results indicate that S in the PM_{2.5} fraction, or correlated air pollutants, may
1116
1117 449 contribute to increased risk of cancer of the stomach.

Particulate matter air pollution components and incidence of cancers of the stomach and the upper aerodigestive tract in the European Study of Cohorts of Air Pollution Effects (ESCAPE)

Gudrun Weinmayr,^{1*} Marie Pedersen,^{2,3} Massimo Stafoggia,^{4,5} Zorana J Andersen,² Claudia Galassi,⁶ Jule Munkenast,¹ Andrea Jaensch,¹ Bente Oftedal,⁷ Norun H Krog,⁷ Geir Aamodt,⁸ Andrei Pyko,⁵ Göran Pershagen,⁵ Michal Korek,⁵ Ulf De Faire,⁵ Nancy L Pedersen,⁹ Claes-Göran Östenson,¹⁰ Debora Rizzuto,¹¹ Mette Sørensen,³ Anne Tjønneland,³ Bas Bueno-de-Mesquita,¹² Roel Vermeulen,^{13,14,15} Marloes Eeftens,^{15,16,17} Hans Concin,¹⁸ Alois Lang,¹⁹ Meng Wang,²⁰ Ming-Yi Tsai,^{16,17,20} Fulvio Ricceri,^{21,22} Carlotta Sacerdote,⁶ Andrea Ranzi,²³ Giulia Cesaroni,⁴ Francesco Forastiere,⁴ Kees de Hoogh,^{16,17} Rob Beelen[†],^{15,2} Paolo Vineis,^{13,25} Ingeborg Kooter,²⁶ Ranjeet Sokhi,²⁷ Bert Brunekreef,^{12,15} Gerard Hoek,¹⁵ Ole Raaschou-Nielsen,^{3,28} and Gabriele Nagel.^{1,18}

¹Institute of Epidemiology and Medical Biometry, Ulm University, Ulm, Germany (G Weinmayr, G Nagel, A Jaensch, J Munkenast);

²Section of Environmental Health, Department of Public Health, University of Copenhagen, Copenhagen, Denmark (M Pedersen, Z J Andersen);

³The Danish Cancer Society Research Center, Copenhagen, Denmark (M Pedersen, O Raaschou-Nielsen, M Sørensen, A Tjønneland);

⁴Department of Epidemiology, Lazio Regional Health Service, ASL Roma 1, Rome, Italy (M Stafoggia, F Forastiere, G Cesaroni);

⁵Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden (U De Faire, M Korek, G Pershagen, A Pyko, M Stafoggia)

⁶Unit of Cancer Epidemiology, Città della Salute e della Scienza University-Hospital and Center for Cancer Prevention (CPO), Turin, Italy (C Galassi, F Ricceri, C Sacerdote);

⁷Norwegian Institute of Public Health, Oslo, Norway (B Oftedal, N H Krog);

⁸Department of Public Health Science, LANDSAM, NMBU, Ås, Norway (G Aamodt)

⁹Department of Medical Epidemiology and Biostatistics (N L Pedersen);

¹⁰Department of Molecular Medicine and Surgery (C-G Östenson);

¹¹Aging Research Center, Department of Neurobiology Care Science and Society , Karolinska Institutet and Stockholm University, Stockholm, Sweden (D Rizzuto);

¹²Department of Epidemiology and Biostatistics, School of Public Health, Imperial College, London, UK (B Bueno-de-Mesquita)

¹³Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht (R Vermeulen, B Brunekreef);

¹⁴MRC-PHE Centre for Environment and Health, Department of Epidemiology and Biostatistics, School of Public Health, Imperial College, London, UK (R Vermeulen, P Vineis)

¹⁵Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands (B Brunekreef, R Beelen, G Hoek, R Vermeulen, M Eeftens);

¹⁶Swiss Tropical and Public Health Institute, Basel, Switzerland; University of Basel, Basel, Switzerland (M Eeftens, K de Hoogh, M-Y Tsai);

¹⁷University of Basel, Basel, Switzerland (M Eeftens , K de Hoogh , M-Y Tsai);

¹⁸Agency for Preventive and Social Medicine, Bregenz (aks), Austria (G Nagel, H Concin);

¹⁹Vorarlberg cancer registry; Agency for Preventive and Social Medicine, Bregenz (aks), Austria (A Lang);

²⁰Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, USA (M Wang, M-Y Tsai);

²¹Unit of Epidemiology, Regional Health Service ASL TO3, Grugliasco, Italy (F Ricceri);

²²Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy;

²³Environmental Health Reference Centre, Regional Agency for Environmental Prevention of Emilia-Romagna, Modena, Italy (A Ranzi);

²⁴National Institute for Public Health and the Environment (RIVM), Bilthoven, The Netherlands (R Beelen);

²⁵Molecular end Epidemiology Unit, HuGeF, Human Genetics Foundation, Torino, Italy (P Vineis);

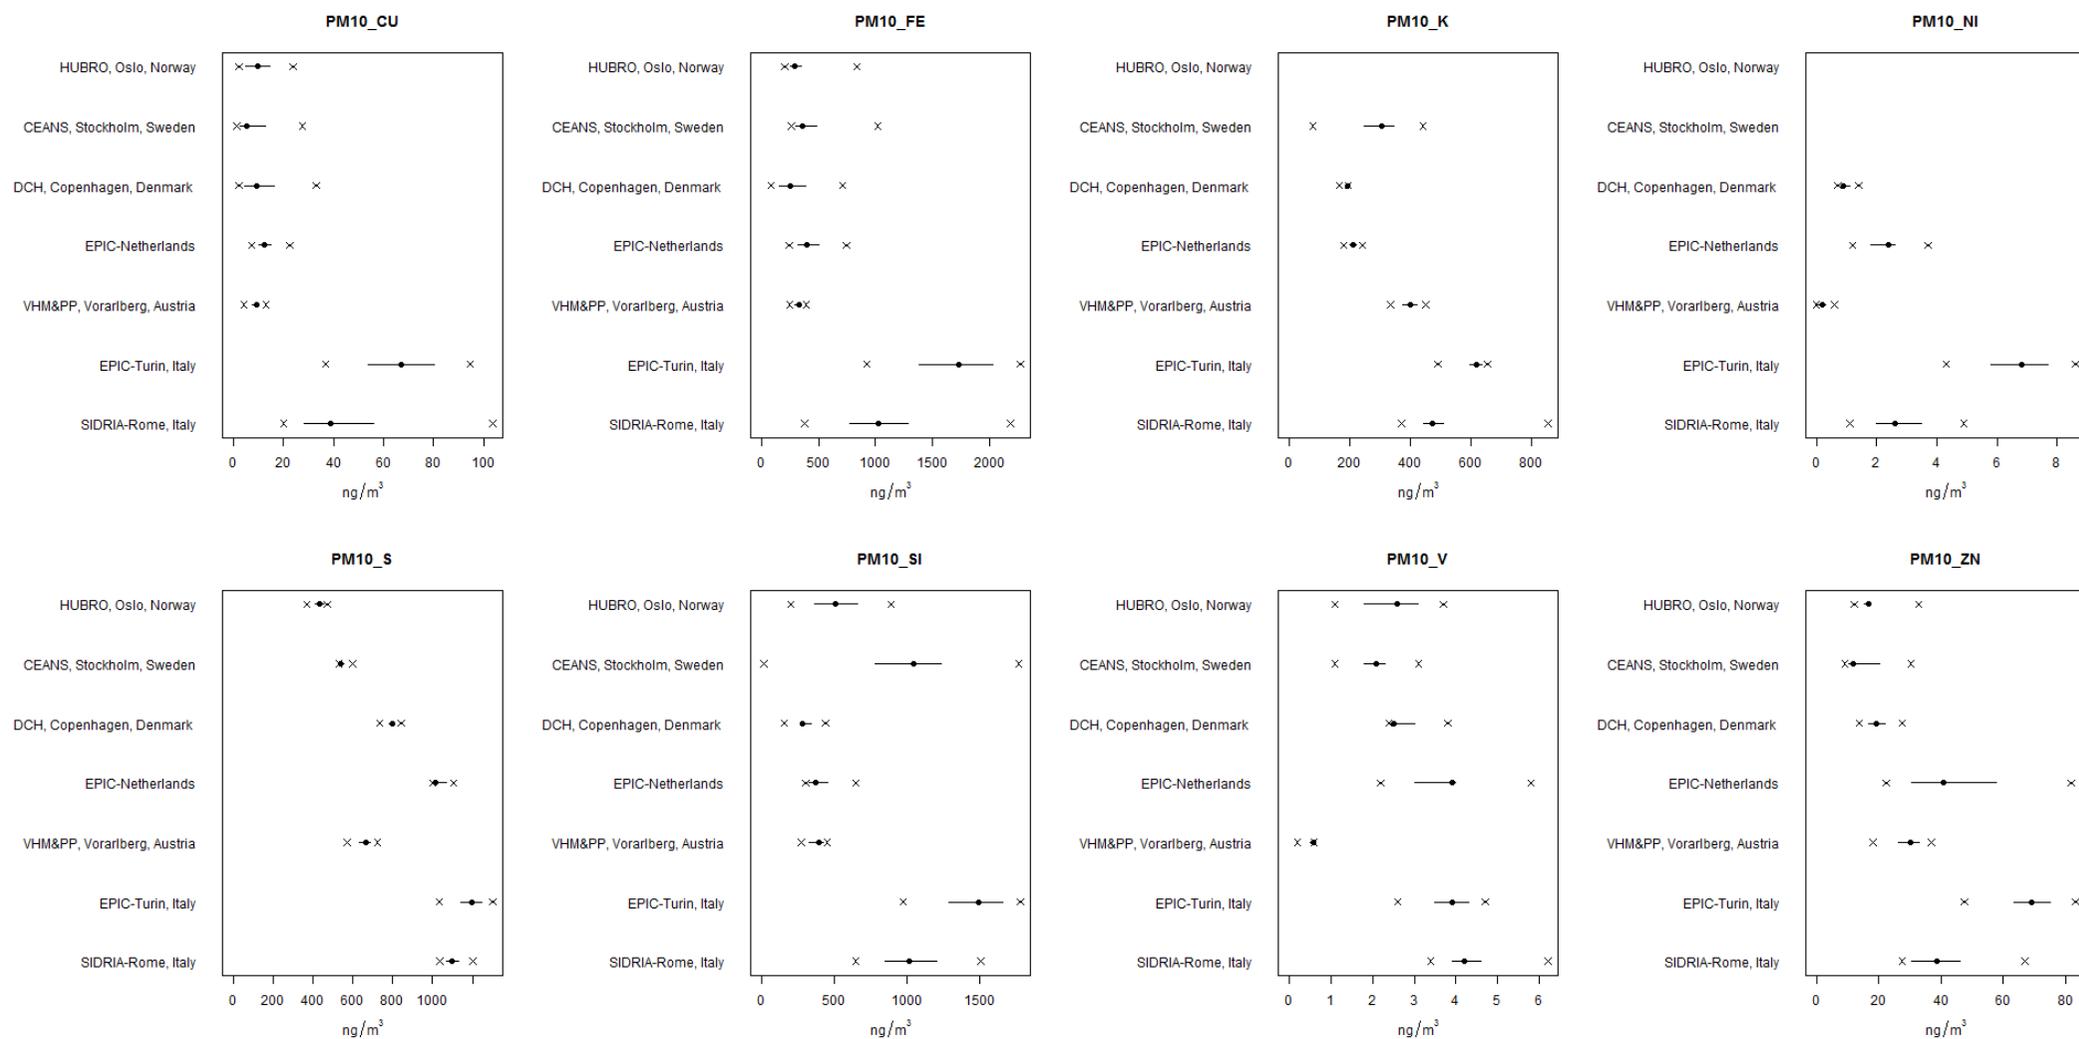

²⁶Netherlands Organization for Applied Scientific Research, Utrecht, The Netherlands (I Kooter)

²⁷Centre for Atmospheric and Climate Physics Research (CACP), University of Hertfordshire, Hatfield, UK (R Sokhi)

²⁸Department of Environmental Science, Aarhus University, Roskilde, Denmark (O Raaschou-Nielsen).

[†] This paper is dedicated to Rob Beelen who was the coordinating PostDoc of ESCAPE and who died far too early in September 2017. He will live in our memories as a great scientist and precious colleague - and a wonderful person.

Supplementary Figure: Estimated annual mean concentration (ng/m³) of PM₁₀ elemental components at participants' addresses in each cohort. The solid circles and bars show the median and 25% and 75% percentile concentrations; the x shows the 5% and 95% percentile values.

Supplementary Table: Results of the random effects meta-analyses of associations between PM₁₀ elemental components and the risk for gastric and UADT cancer

PM₁₀=particulate matter with diameter <10 μm . We included only participants without missing data in any of the variables included in model 3, so the datasets were identical for analyses with all three models. HR=hazard ratio. UADT= upper aerodigestive tract. § relating to model 3 *Model 1: age (timescale in Cox model), sex, calendar time. †Model 2: model 1 + smoking status, smoking intensity, smoking duration, occupational exposure, employment status and educational level. ‡Model 3: model 2 + area-level (residential neighborhood or similar) socio-economic status. 1: without CEANS. 2: without HUBRO. 3: without HUBRO, VHM&PP.
